Events in Node.js

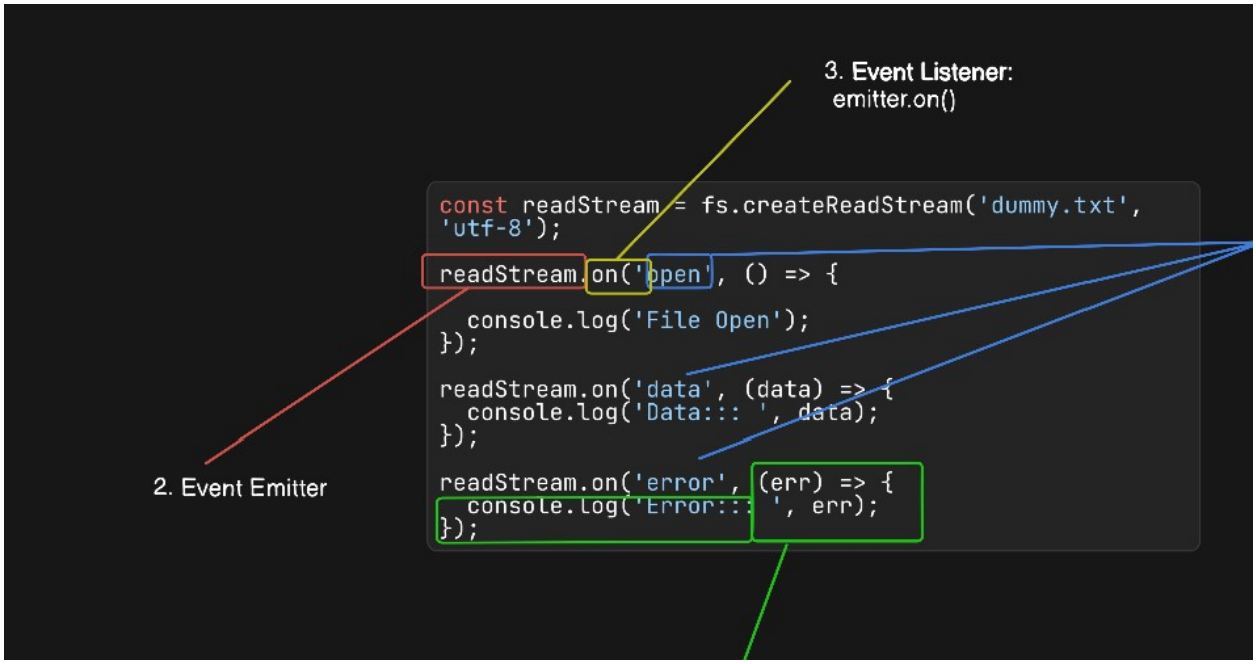

Basic Terminologies

In **event-driven programming** (especially in ecosystems like Node.js* and DOM events), these four terms form the core lifecycle of how an application reacts to changes

1. **Event:** An **event** is something that happens in your application.
2. **Event Emitter:** An **Event Emitter** is an object that **creates/emits events** and allows other code to listen for them.
3. **Event Listener:** An **Event Listener** is code that **waits for a particular event**.
4. **Event Handler:** An **Event Handler** is the **function that runs when the event occurs**.

Example:

Reference: Fs -> createReadStreams

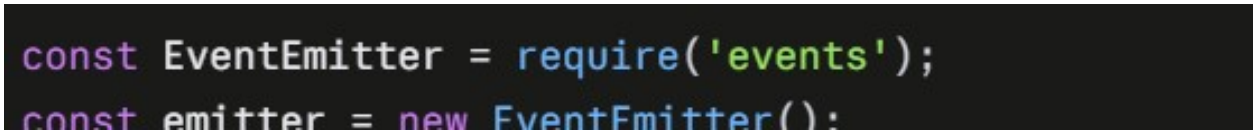

EventEmitter

EventEmitter is a class from Node's built-in events module that lets objects communicate through named events.

- EventEmitter (to create instance)
- Emitter.on() : Listener
- Emitter.emit(): Emitter

The three pieces

1. **Create Instance**

2. ***emitter.on(eventName, listener)*** **registers a listener function.**

3. ***emitter.emit(eventName, ...args)*** triggers the event.
